Abstract

Forensic anthropology has evolved significantly, from traditional skeletal analysis to a highly interdisciplinary science, enriched by advances in imaging, molecular biology and digital technology. The purpose of this scoping review is to examine and synthesise the latest developments in forensic anthropology over the last five years, highlighting key innovations, challenges and future directions. A comprehensive search was made using the databases of PubMed, Medline and Research Gate, using keywords such as forensic anthropology, identification, DNA, and age estimation and a final selection of 41 peer reviewed papers were included.

The review divides the findings into several areas: age and gender estimates, DNA and biomolecular techniques, trauma analysis, virtual anthropology, taphonomy, and ethical considerations. Technologies such as post-mortem CT, 3D imaging, photogrammetry and artificial facial reconstruction are now widely integrated in forensic practice. In addition, the use of microbiomes and orthopaedic implants for identification of difficult cases is being increasingly explored. The ethical and legal frameworks governing the treatment of human remains and digital data have also become more prominent.

Geographically, the majority of contributions come from the US and Europe, with research emerging in Asia. While methodological progress has been remarkable, differences in global standardisation and availability of modern tools persist. This review highlights the need for cross-disciplinary cooperation, training and adherence to ethical standards in order to further strengthen forensic anthropology as a key pillar of the medical-legal system.

Keywords: Forensic Anthropology, Human Identification,3D Imaging, DNA Analysis, Taphonomy, Scoping review.

Introduction

Forensic anthropology is an applied scientific discipline dedicated to identifying unidentified human remains, whether skeletal or in advanced decomposition. It covers a wide range of topics from human physiognomy to osteology and, being multidisciplinary, requires cooperation with other specialized groups. [1]

Since its formal introduction over 80 years ago, forensic anthropology has expanded significantly. Its scope now includes trauma analysis, taphonomy and the increasing involvement of forensic anthropologists in large scale investigations, such as cases of missing or disappeared individuals. Forensic anthropologists also assist in location and recovering remains, often using subdisciplines like forensic archaeology. More recently, practitioners have begun to recognize the importance of ethics in forensic anthropology, emphasizing respectful handling of remains, the professional conduct of experts and the responsible use of technology in the discipline. [2]

Forensic anthropologists utilize traditional techniques to estimate age, sex, race, stature etc using outdated tools like osteometric boards, sliding calipers but now their role extends beyond

© Author(s) 2026. Published by the Academy Journal of Forensic Medicine (ISSN: 3107-7633). traditional identification by integrating with subdisciplines like forensic archaeology in systematic search, proper retrieval of skeleton, detecting trauma patterns to determine the cause, manner of death and postmortem interval (PMI) estimation by studying human cadaver from crime scene to autopsy suites to reconstruct life history and death circumstances [3-6.]

Forensic anthropology has become a mature scientific field, continuously evolving through innovative, globally-driven research that applies anthropological knowledge to medico-legal problems. With its expanding reach into both established and emerging domains, the demand for high-quality expertise must be supported by continuous education and modernized scientific methods. [3]

Objective

To explore the review of literature on emerging scientific wide array of methods, advancements of anthropology in a forensic perspective during the recent five years methodology

Search strategy

A digital search of Pub Med, Medline and Research Gate was performed along with a manual search of reference lists of relevant articles.

Search/key words

Forensic Anthropology, Recent advances, Forensic, Identification, Wars, Human remains, DNA, Sex, Age, Decomposition

Filters

5 years, Free full text, Articles in English language

Selection Criteria

Articles read in full for the final inclusion and excluded Duplicates, irrelevant articles. The search retrieved 204 results. Of the 204 articles,163 duplicates or irrelevant articles/ eliminated. Results were then refined by their title and abstract. The reference list of all identified articles was further manually searched for additional articles. This process of refining and excluding eventually left a total number of 41 articles. (Fig: 1)

Results

The study was organized into the following key thematic areas.

1. Technological Innovations: The integration of 3D imaging, structured light scanning, photogrammetry and CT has revolutionized the estimation of age and gender. Software tools such as photoshop and blender software are now used for facial similarity reconstruction. Virtual repositories and digital bone collections (e.g. Smithsonian 3D, IMPACT) facilitate global cooperation.
2. DNA and Biomolecular Techniques: The DNA extraction from small or highly degraded samples allows for ancestry and phenotypic analysis. The forensic microbiome is being explored to estimate post-mortem interval and biological sex. Orthopaedic implants, which can be traced through serial numbers, provide valuable leads for identification.
3. Age and Sex Estimation Methods: Acetabular and arthritic changes provide a more accurate estimate of adult age. Ridge density analysis and sinus morphology are increasingly employed for determining gender. PMCT and digital morphometry enhance the precision of stature estimation.
4. Trauma and Pathology Analysis: Advances in pattern recognition of fractures and burn analysis have improved identification in burn

Screening Process for Article Selection:

Included
Studies included in qualitative synthesis (n=41)

(Fig: 1) shows flow diagram of screening process

victims. The biomechanics of skull fractures are now digitally modelled for forensic interpretation.

5. Taphonomy and Decomposition Research: Devices such as ARISTA (Netherlands) and those at the University of Tennessee are used for controlled decomposition studies. Remote sensing and minimally invasive techniques enable the detection of grave sites without exhumation.
6. Ethical and Legal Challenges: Global disparities exist in the legal responsibilities for forensic analysis (e.g. the Swiss model supervised by a legal doctor). Ethics guidelines have emerged for the digital facial reconstruction and the respectful handling of virtual remains.
7. Interdisciplinary Collaboration: Multi disciplinary teams involving DNA experts, anthropologists, dentists and pathologists collaborate in the Disaster Victim identification (DVI). The Interpol DVI protocol promotes standardised international practices.
8. Geographic and Temporal Trends: Region-wise, most innovation stems from the U.S., Australia, and Europe, particularly in digital forensics and decomposition research. Asia is contributing population-specific studies, though still limited in volume.
9. Year-wise Analysis: Peak publishing activity occurred between 2019 and 2022, with a noticeable shift from basic anthropometric methods to more advanced biometrics and digital techniques.

Discussion

Age Estimation

Age estimation continues to be pivotal in forensic anthropology, especially in legal contexts such as migration, adoption, child pornography, criminal behavior, and missing persons. Key advances include: 1. Technological Integration: Digital technology like 3D facial prototypes and improved image-processing has enhanced the age estimation (Matthews et al.) [7]. 2. Taphonomic Influences: Studies reported that thermal damage severely affects bone and dental structures and its preservation challenges are critical (Cappella et al. [8] and Adserias Garriga et al. [9]. 3. New Anatomical Markers: Research into acetabulum and its arthritic changes has improved post-mortem age estimation. (Alves-Cardoso & Assis) [10]. 4. Standardization Efforts: The Scientific Working Group for Forensic Anthropology (SWGANTH) [11] emphasizes skeletal system remains as foundational for age estimation protocols.

Sex Estimation

Sex estimation remains a critical first step in biological profiling. Recent developments include: Osteological and Dental Techniques: Traditional methods are still used, but problems remain due to the subjective nature of morphological (non-metric) assessments and the labor-intensive nature of morphometric methods. 3D Imaging advances: Tools such as Intelli Space ® and In Vesalius® enable reproducible and high-resolution assess ments. [12] Dimorphism studies: High accuracy was reported for the pelvis (up to 94%), skull, hyoid, ribs, ulna and metatarsus (up to 94 percent). [13] Fingerprint Ridge Density (FPRD): is gaining because of its population-specific and indivi dualistic properties. [14]

Maxillary Sinus Analysis: CT-based maxillary sinus evaluation provides high accuracy for sex determination, particularly when only fragmentary remains are available. [15]

Stature Estimation:

PMCT offers high resolution imaging and precise measurements without physical handling of the remains, which is an advantage in regions with limited access to skeletal remains. [16]

Decomposition: Decomposition Research Centers in the US, Europe and Australia facilitated semi-controlled trails on post-mortem interval intervals (PMI) under diverse environmental condi tions. [17] ARISTA Facility for Sub-surface Taphonomy and Anthropology employs grave monitoring, remote sensing, and minimally invasive methods to investigate human decomposition. [18] Skeletal Remains Analysis: Historical and modern skeletal remains provide insights into Post-War Identification with improved archival integration and DNA comparison techniques. [19] Burned Remains now leverages heat-induced color gradations (Munsell scale) to reconstruct body positioning and burn dynamics. [20] DNA Recovery: Technological advances now allow DNA profiling of small or degraded bone samples, which helps to

predict ancestry and phenotypic traits. [21]

Virtual Anthropology: Digital advancements have redefined skeletal analysis: 3D Reconstruction: Instruments such as CT, Structured Light Scans (SLS) and laser scanning, generate virtual bone models that optimize the reconstruction of fragmentary remains. Photogrammetry: Cost-effective 3D scanning with DSLR cameras and software such as Agisoft Metashape provides high-resolution virtual bone models[22]. Digital Repositories: Collections like Smithsonian 3D collection and the IMPACT radiologic mummy database offer worldwide access to digitized skeletal samples.

Identification: Facial approximation: Digital reconstruction like eg. Autodesk recap studio Inc™, Blender Foundation™ which determines the steps and the sequence to recreate a face. The soft tissue table was developed by Beaini in a Brazilian for the same region of the skulls for similar purpose. [12] Role of Microbiome: Human DNA can remain unchanged for years and extracts stored at − 20 ◦C or − 80 ◦C can preserve important genetic information for long periods and can be submitted as evidence in court. The composition of the postmortem microbiome differs by biological sex, with Pseudomonas sp. only identified in female cadavers, and Rothia sp. only in male cadavers. The microbial signatures also help in PMI estimation. [23] Craniofacial superimposition: It assist in identification of human skeletal remains when methods of DNA, radiographic comparison and fingerprints cannot be used, relying on photographic overlays rooted in optical physics. [24]

Orthopedic Surgical Implants in Identification: In challenging circumstances when conventional methods of identification like DNA analysis, fingerprints and dental charting are not applicable where visual identity compromised as in dismembered body or skeletal remains in disaster victim identification or excessive thermal alteration cases, Orthopedic surgical implantable devices provide variable and valuable information that helps in identification. [25] Disaster Victim Identification: DVI processes requires collaborative forensic expertise In countries like Switzerland, legal mandates assign DVI duties to forensic pathologists. Interpol DVI, guide standardizes international procedures, ensure appropriate software use, validation and multidisciplinary training. [26]

Osteological Ageing from Digital Data: 3D technologies like laser scanners, CT and micro CT scanners have enabled digital analysis of skeletal remains. Some notable examples of digital collections are the University of Bradford's "From Cemetery to Clinic" and the "Smithsonian's 3D-Digitization" and "Digitized Diseases" and IMPACT Radiological Mummy Database created high quality datasets on the deceased which support forensic casework. (Villa C et al. [10] and Shearer et al. [27]).

Ethics: Ethical dilemmas include issues consent, cultural beliefs and digital replication., As outlined by Marquez-Grant ´ et al [28], questions arise around ownership of data, and presentation of sensitive material. The BABAO guidelines support 3D imaging for educational display, yet concerns regarding equivalency remains. [29] Ultimately, balancing scientific advancement with respect for the deceased and cultural sensitivities is essential to uphold ethical integrity in forensic anthropology.

Conclusion

Forensic Anthropology is undergoing significant advancements which necessitates further studies and research with proper guidelines, in expanding the professional practice of forensic faculty worldwide, for the betterment of the medico-legal system. The multitude of methods tested and the continuous development of new techniques-especially computer aided technologies, high-quality radiological imaging and advances in forensic research fields related to anthropology have improved over the last years and probably continue to do so in the future. Adequate training and funding must be provided to ensure that sound research, based upon the scientific method, remains the cornerstone of advancement in Anthropology specifically in forensic perspective.

Last but not the least, the development of forensic anthropology often depends on a country's legal framework, the volume and typology of forensic casework, and its forensic and educational traditions.
